# Chapter 10: Storage and File Structure

- File Organization
- Organization of Records in Files

# **File Organization, Record Organization and Storage Access**

# File Organization

- The database is stored as a collection of *files*. Each file is a sequence of *records*. A record is a sequence of fields.
- One approach:
  - assume record size is fixed
  - each file has records of one particular type only
  - different files are used for different relations

This case is easiest to implement; will consider variable length records later.

# Fixed-Length Records

## ■ Simple approach:

- Store record  $i$  starting from byte  $n * (i - 1)$ , where  $n$  is the size of each record.
- Record access is simple but records may cross blocks
  - ▶ Modification: do not allow records to cross block boundaries

## ■ Deletion of record $i$ : alternatives:

- move records  $i + 1, \dots, n$  to  $i, \dots, n - 1$
- move record  $n$  to  $i$
- do not move records, but link all free records on a *free list*

# Free Lists

- Store the address of the first deleted record in the file header.
- Use this first record to store the address of the second deleted record, and so on
- Can think of these stored addresses as **pointers** since they “point” to the location of a record.
- More space efficient representation: reuse space for normal attributes of free records to store pointers. (No pointers stored in in-use records.)

# Variable-Length Records

- Variable-length records arise in database systems in several ways:
  - Storage of multiple record types in a file.
  - Record types that allow variable lengths for one or more fields such as strings (**varchar**)
  - Record types that allow repeating fields (used in some older data models).
- Attributes are stored in order
- Variable length attributes represented by fixed size (offset, length), with actual data stored after all fixed length attributes
- Null values represented by null-value bitmap

# Variable-Length Records: Slotted Page Structure

- **Slotted page** header contains:
  - number of record entries
  - end of free space in the block
  - location and size of each record
- Records can be moved around within a page to keep them contiguous with no empty space between them; entry in the header must be updated.
- Pointers should not point directly to record — instead they should point to the entry for the record in header.

# Organization of Records in Files

- **Heap** – a record can be placed anywhere in the file where there is space
- **Sequential** – store records in sequential order, based on the value of the search key of each record
- **Hashing** – a hash function computed on some attribute of each record; the result specifies in which block of the file the record should be placed
- Records of each relation may be stored in a separate file. In a **multitable clustering file organization** records of several different relations can be stored in the same file
  - Motivation: store related records on the same block to minimize I/O

# Sequential File Organization

- Suitable for applications that require sequential processing of the entire file
- The records in the file are ordered by a **search-key**

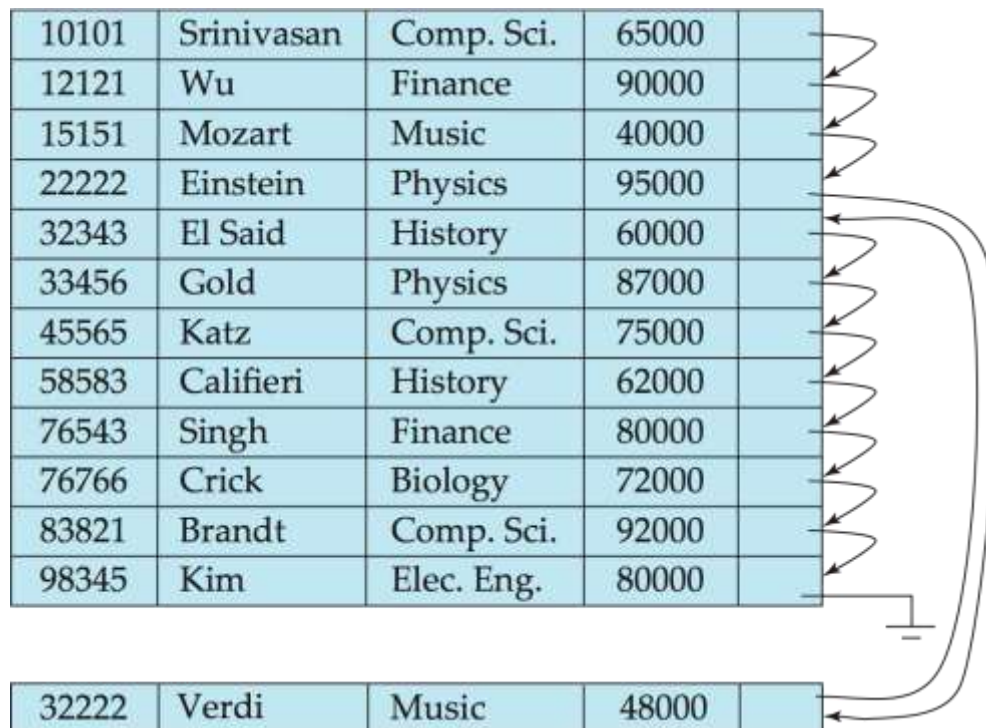

10101	Srinivasan	Comp. Sci.	65000	
12121	Wu	Finance	90000

83821	Brandt	Comp. Sci.	92000	
98345	Kim	Elec. Eng.	80000	

# Sequential File Organization (Cont.)

- Deletion – use pointer chains
- Insertion – locate the position where the record is to be inserted
  - if there is free space insert there
  - if no free space, insert the record in an **overflow block**
  - In either case, pointer chain must be updated
- Need to reorganize the file from time to time to restore sequential order

# Multitable Clustering File Organization

Store several relations in one file using a **multitable clustering** file organization

*department*

# Multitable Clustering File Organization (cont.)

- good for queries involving *department* ⋈ *instructor*, and for queries involving one single department and its instructors
- bad for queries involving only *department*
- results in variable size records
- Can add pointer chains to link records of a particular relation
