# Module 4

**Network Layer** 

## Module 4: outline

#### 4.1 Introduction

- 4.2 Virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
  - datagram format
  - IPv4 addressing
  - ICMP
  - IPv6

- 4.5 routing algorithms
  - link state
  - distance vector
- 4.6 routing in the Internet
  - RIP
  - OSPF
  - BGP

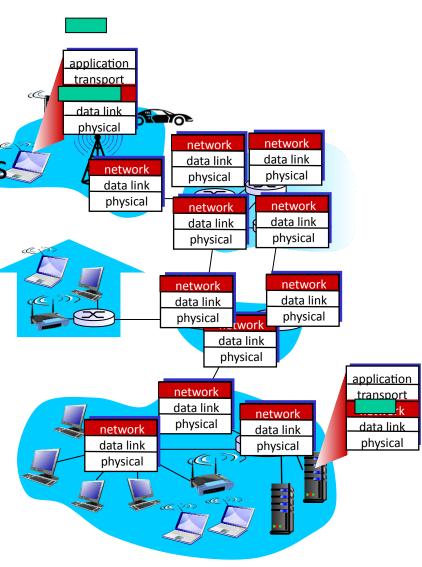

### Network layer

transport segment from sending to receiving host

on sending side encapsulates segments into datagrams

on receiving side, delivers segments to transport layer

- network layer protocols in every host, router
- router examines header fields in all IP datagrams passing through it

# Two key network-layer functions

- \* forwarding: move packets from router's input to appropriate router output
- \* routing: determine route taken by packets from source to dest.
  - routing algorithms

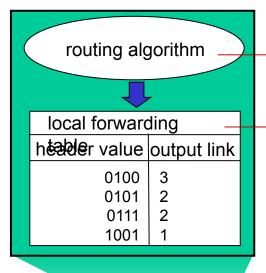

forwarding

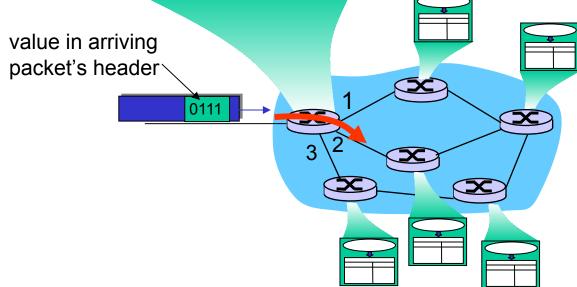

routing

#### Interplay between routing and forwarding

routing algorithm determines end-end-path through network

forwarding table determines local forwarding at this router

## Connection setup

- \* 3<sup>rd</sup> important function in *some* network architectures:
  - ATM, frame relay, X.25
- before datagrams flow, two end hosts and intervening routers establish virtual connection
  - routers get involved
- network vs transport layer connection service:
  - network: between two hosts (may also involve intervening routers in case of VCs)
  - transport: between two processes

### Network service model

Q: What service model for "channel" transporting datagrams from sender to receiver?

# example services for individual datagrams:

- guaranteed delivery
- guaranteed delivery with (bounded)delay

# example services for a flow of datagrams:

- in-order datagram delivery
- guaranteed minimum bandwidth to flow.
- Guaranteed maximum jitter
- Security services

specific services that could be provided by the network layer

### Network layer service models:

Network Architecture	Service Model	Bandwidth Guarantee	No-Loss Guarantee	Ordering	Timing	Congestion Indication
Internet	Best Effort	None	None	Any order possible	Not maintained	None
ATM	CBR	Guaranteed constant rate	Yes	In order	Maintained	Congestion will not occur
ATM	ABR	Guaranteed minimum	None	In order	Not maintained	Congestion indication provided

# Chapter 4: outline

- 4.1 introduction
- 4.2 virtual circuit and datagram networks
- 4.3 what's inside a router
- 4.4 IP: Internet Protocol
  - datagram format
  - IPv4 addressing
  - ICMP
  - IPv6

- 4.5 routing algorithms
  - link state
  - distance vector
  - hierarchical routing
- 4.6 routing in the Internet
  - RIP
  - OSPF
  - BGP
- 4.7 broadcast and multicast routing

#### Connection, connection-less service

- datagram network provides network-layer connectionless service
- virtual-circuit network provides network-layer connection service
- analogy to TCP/UDP connection-oriented / connectionless transport-layer services, but:
  - service: host-to-host
  - no choice: network provides one or the other
  - implementation: in network core

### Virtual circuits

"source-to-dest path behaves much like telephone circuit"

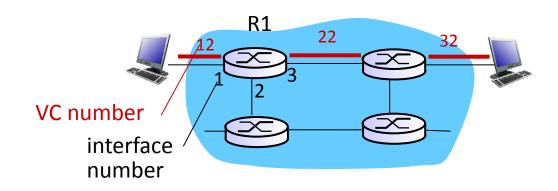

- performance-wise
- network actions along source-to-dest path
- \* call setup, teardown for each call before data can flow
- each packet carries VC identifier (not destination host address)
- every router on source-dest path maintains "state" for each passing connection
- link, router resources (bandwidth, buffers) may be allocated to VC (dedicated resources = predictable service)

# VC implementation

#### a VC consists of:

- 1. path from source to destination
- 2. VC numbers, one number for each link along path
- 3. entries in forwarding tables in routers along path
- packet belonging to VC carries VC number (rather than dest address)
- VC number can be changed on each link.
  - new VC number comes from forwarding table

# VC forwarding table

forwarding table in northwest router:

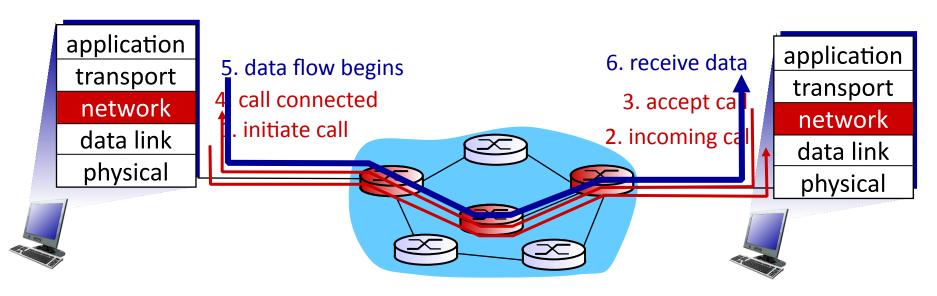

Incoming interface	Incoming VC #	Outgoing interface	Outgoing VC #	
1	12	3	22	
2	63	1	18	
3	7	2	17	
1	97	3	87	
•••	•••	•••		

VC routers maintain connection state information!

#### Virtual circuits

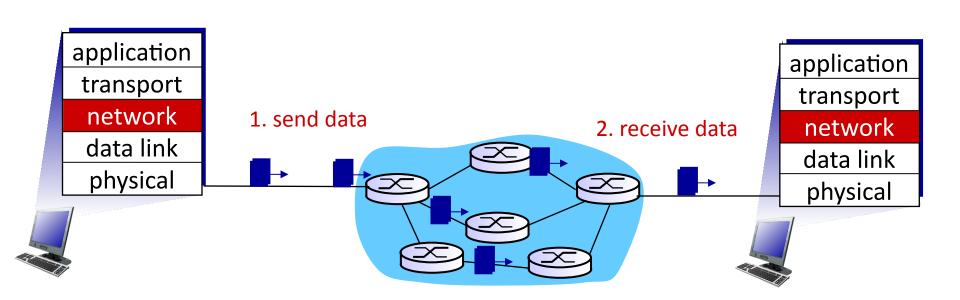

- signaling protocols used to setup, maintain teardown VC
- used in ATM, frame-relay, X.25
- not used in today's Internet

Virtual-circuit setup

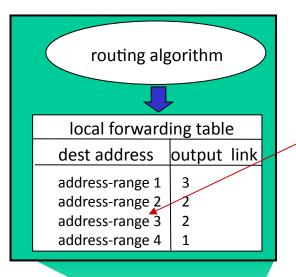

### Datagram networks

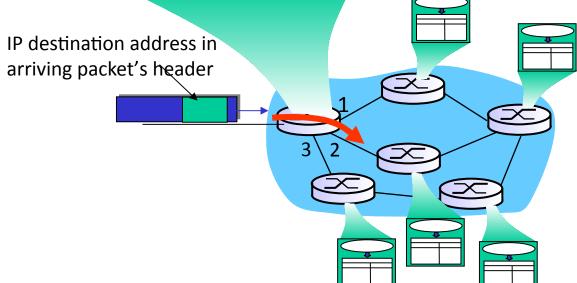

- no call setup at network layer
- routers: no state about end-to-end connections
  - no network-level concept of "connection"
- packets forwarded using destination host address

### Datagram forwarding table

4 billion IP addresses, so rather than list individual destination address list *range* of addresses (aggregate table entries)

#### Figure 4.3: A connectionless packet-switched network

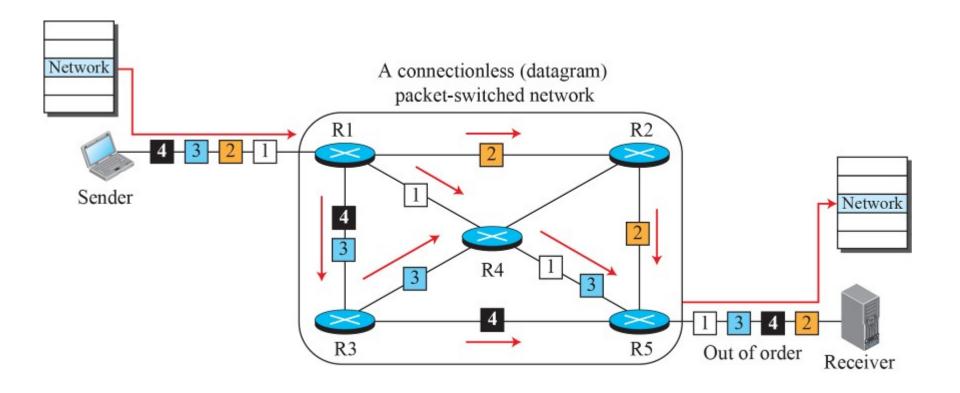

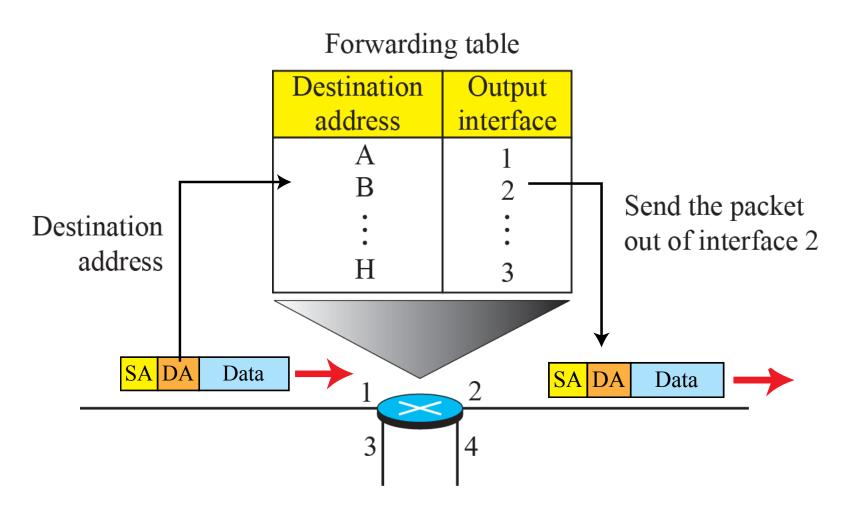

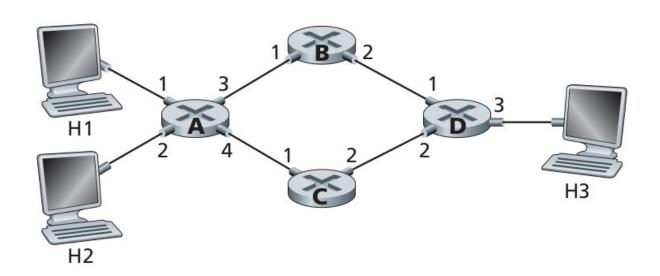

Figure 4.4: Forwarding process in a router when used in a connectionless network

Consider the network below.

- a. Suppose that this network is a datagram network. Show the forwarding table in router A, such that all traffic destined to host H3 is forwarded through interface 3.
- b. Suppose that this network is a datagram network. Can you write down a forwarding table in router A, such that all traffic from H1 destined to host H3 is forwarded through interface 3, while all traffic from H2 destined to host H3 is forwarded through interface 4? (Hint: this is a trick question.)
- c. Now suppose that this network is a virtual circuit network and that there is one ongoing call between H1 and H3, and another ongoing call between H2 and H3. Write down a forwarding table in router A, such that all traffic from H1 destined to host H3 is forwarded through interface 3, while all traffic from H2 destined to host H3 is forwarded through interface 4.
- d. Assuming the same scenario as (c), write down the forwarding tables in nodes B, C, and D.

Suppose there are three routers between a source host and a destination host. Ignoring fragmentation, an IP datagram sent from the source host to the destination host will travel over how many interfaces? How many forwarding tables will be indexed to move the datagram from the source to the destination?

### Datagram forwarding table

Destination Address Range	Link Interface
11001000 00010111 00010000 00000000 through 11001000 00010111 00010111 11111111	0
11001000 00010111 00011000 00000000 through 11001000 00010111 00011000 11111111	1
11001000 00010111 00011001 00000000 through 11001000 00010111 00011111 11111111	2
otherwise	3

Q: but what happens if ranges don't divide up so nicely?

Destination Address Range	Interface
200.23.16.0 - 200.23.23.255	0
200.23.24.0 - 200.23.24.255	1
200.23.25.0 - 200.23.31.255	2
Otherwise	3

# Longest prefix matching

#### longest prefix matching

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range	Link interface
11001000 00010111 00010*** ******	0
11001000 00010111 00011000 *******	1
11001000 00010111 00011*** *******	2
otherwise	3

#### examples:

DA: 11001000 00010111 0001011<mark>0 10100001</mark>

DA: 11001000 00010111 00011000 10101010

which interface?

Consider a datagram network using 8-bit host addresses.
Suppose a router uses longest-prefix matching, and has the following forwarding table:

Prefix Match	Interface
00	1
10	2
001	3
101	4
110	5
otherwise	6

- 1. Suppose a datagram arrives at the router, with destination address 00000110. To which interface will this datagram be forwarded using longest-prefix matching?
- 2. Suppose a datagram arrives at the router, with destination address 10010000. To which interface will this datagram be forwarded using longest-prefix matching?
- 3. Suppose a datagram arrives at the router, with destination address 00010111. To which interface will this datagram be forwarded using longest-prefix matching?

Consider a datagram network using 8-bit host addresses. Suppose a router uses longest-prefix matching, and has the following forwarding table:

Prefix Match	Interface
00	1
10	2
001	3
101	4
111	5
otherwise	6

- 1. Suppose a datagram arrives at the router, with destination address 11011101. To which interface will this datagram be forwarded using longest-prefix matching?
- 2. Suppose a datagram arrives at the router, with destination address 01011100. To which interface will this datagram be forwarded using longest-prefix matching?
- 3. Suppose a datagram arrives at the router, with destination address 01001011. To which interface will this datagram be forwarded using longest-prefix matching?

Consider a datagram network using 32-bit host addresses. Suppose a router has four links, numbered 0 through 3, and packets are to be forwarded to the link interfaces as follows:

Destination Address Range			Link Interface	
11100000	00000000	00000000	00000000	
	thro	ough		0
11100000	00111111	11111111	11111111	
11100000	01000000 thro	00000000 ugh	00000000	1
11100000	01000000	11111111	11111111	
11100000	01000001 thro		00000000	2
11100001		11111111	11111111	2
	other	wise		3

Provide a forwarding table that uses longest prefix matching, and forwards packets to the correct link interfaces.

Describe how your forwarding table determines the appropriate link interface for datagrams with destination addresses:

11001000 10010001 01010001 01010101

11100001 01000000 11000011 00111100

11100001 10000000 00010001 01110111

Consider a datagram network using 8-bit host addresses. Suppose a router uses longest prefix matching and has the following forwarding table:

Prefix Match	Interface	
00	0	
010	1	
011	2	
10	2	
11	3	

For each of the four interfaces, give the associated range of destination host addresses and the number of addresses in the range.

# Datagram or VC network: why?

#### Internet (datagram)

- data exchange among computers
  - "elastic" service, no strict timing req.
- many link types
  - different characteristics
  - uniform service difficult
- "smart" end systems (computers)
  - can adapt, perform control, error recovery
  - simple inside network, complexity at "edge"

#### ATM (VC)

- evolved from telephony
- human conversation:
  - strict timing, reliability requirements
  - need for guaranteed service
- "dumb" end systems
  - telephones
  - complexity inside network

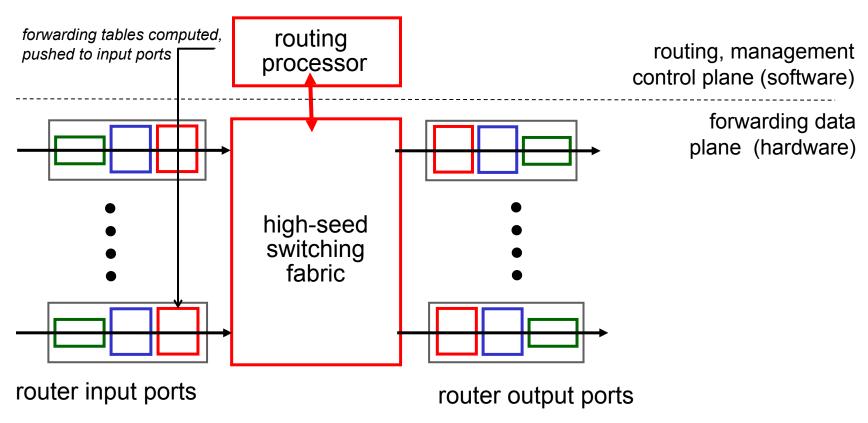

# Chapter 4: outline

- 4.5 noturtidg catigorithms
- 4.2 virtuastetecuit and datagram networks
- 4.3 what's inside a router
- hierarchical routing
- 4.6 routing in the Internet
  - RIP. . . . .
  - Pv4 addressing
  - PSRE
  - BGP
- 4.7 broadcast and multicast routing

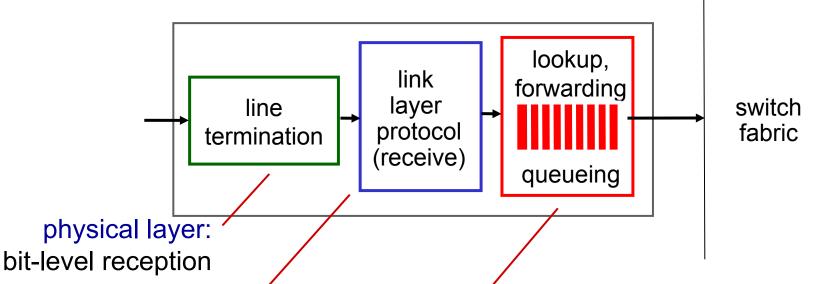

#### Router architecture overview

#### two key router functions:

- run routing algorithms/protocol (RIP, OSPF, BGP)
- \* forwarding datagrams from incoming to outgoing link

### Input port functions

#### data link layer:

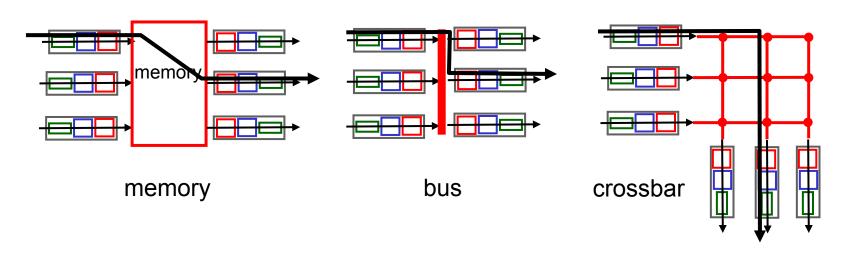

e.g., Ethernet see chapter 5

#### decentralizéd switching:

- given datagram dest., lookup output port using forwarding table in input port memory ("match plus action")
- goal: complete input port processing at 'line speed'
- queuing: if datagrams arrive faster than forwarding rate into switch fabric

### Switching fabrics

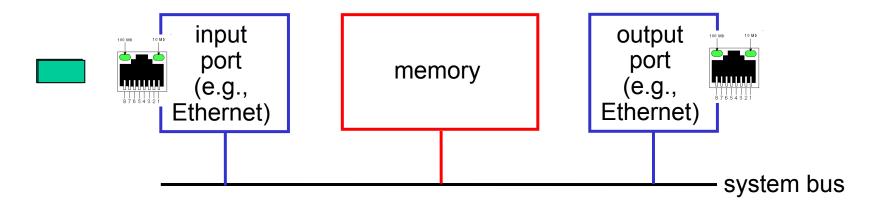

- transfer packet from input buffer to appropriate output buffer
- switching rate: rate at which packets can be transfer from inputs to outputs
  - often measured as multiple of input/output line rate
  - N inputs: switching rate N times line rate desirable
- three types of switching fabrics

### Switching via memory

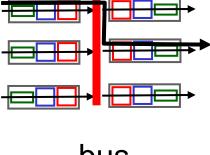

#### first generation routers:

- \* traditional computers with switching under direct control of CPU
- packet copied to system's memory
- speed limited by memory bandwidth (2 bus crossings per datagram)

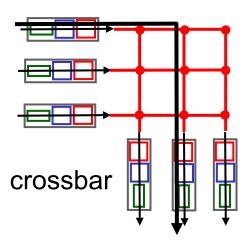

### Switching via a bus

- datagram from input port memory to output port memory via a shared bus
- \* bus contention: switching speed limited by bus bandwidth
- 32 Gbps bus, Cisco 5600: sufficient speed for access and enterprise routers

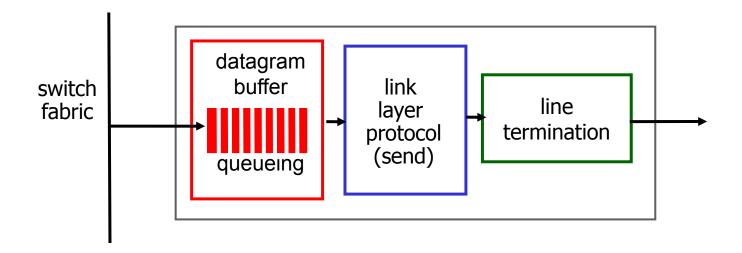

#### Switching via interconnection network

- overcome bus bandwidth limitations
- banyan networks, crossbar, other interconnection nets initially developed to connect processors in multiprocessor
- advanced design: fragmenting datagram into fixed length cells, switch cells through the fabric.
- Cisco 12000: switches 60 Gbps through the interconnection network

### Output ports

#### This slide in HUGELY important!

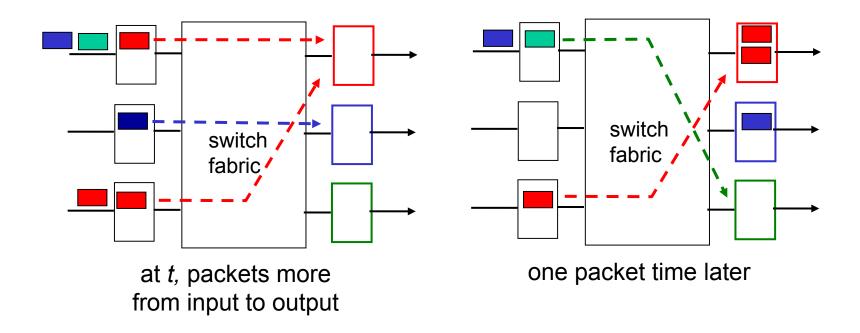

buffering required w fabric faster than the

Datagram (packets) can be lost due to congestion, lack of buffers

\* scheduling discipline chooses among queued datagrams for transmission

Priority scheduling – who gets best performance, network neutrality

### Output port queueing

- buffering when arrival rate via switch exceeds output line speed
- queueing (delay) and loss due to output port buffer overflow!

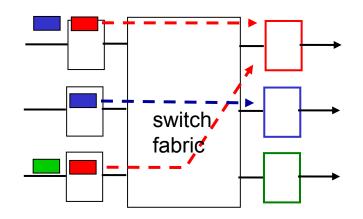

# How much buffering?

- RFC 3439 rule of thumb: average buffering equal to "typical" RTT (say 250 msec) times link capacity C
  - e.g., C = 10 Gbps link: 2.5 Gbit buffer
- recent recommendation: with N flows, buffering equal to

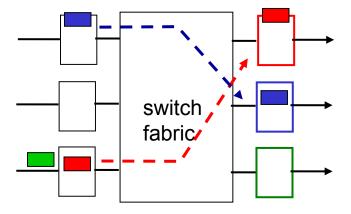

$$\frac{\mathsf{RTT} \cdot \mathsf{C}}{\sqrt{\mathsf{N}}}$$

### Input port queuing

- fabric slower than input ports combined -> queueing may occur at input queues
  - queueing delay and loss due to input buffer overflow!
- \* Head-of-the-Line (HOL) blocking: queued datagram at front of queue prevents others in queue from moving forward

output port contention: only one red datagram can be transferred. *lower red packet is blocked* 

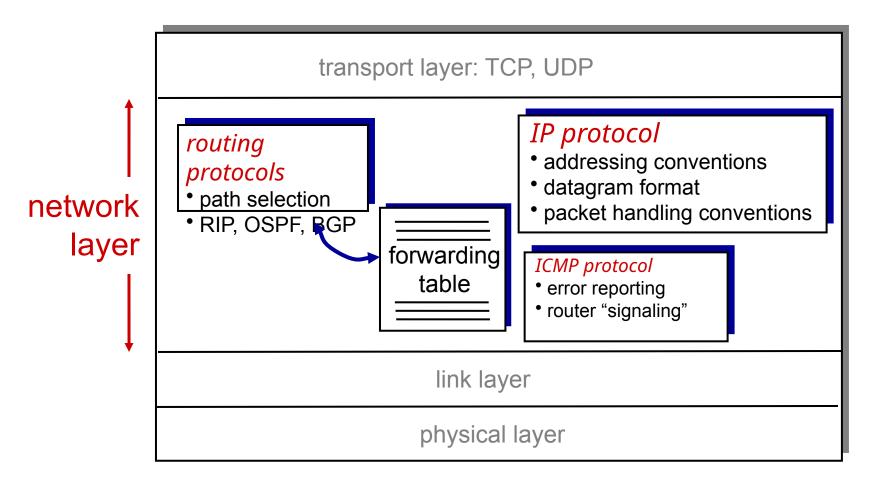

one packet time later: green packet experiences HOL blocking

# Chapter 4: outline

- 4.5 inoturtidg catigorithms
- 4.2 virtuastetecuit and datagram networks
- 4.3 what's inside a router
- 4 4 IP: Internet Protocol
- 4.6 routing in the Internet
  - RIP
  - Pv4 addressing
  - PSMB
  - BGR
- 4.7 broadcast and multicast routing

# The Internet network layer

host, router network layer functions:

## IP datagram format

IP protocol version 32 bits total datagram number` length (bytes) header length type of head. length (bytes) service len for "type" of data fragment flgs fragmentation/ 16-bit identifier offset reassembly max number time to upper header remaining hops live layer checksum (decremented at 32 bit source IP address each router) 32 bit destination IP address upper layer protocol to deliver payload to e.g. timestamp, options (if any) record route data taken, specify (variable length, list of routers typically a TCP

or UDP segment)

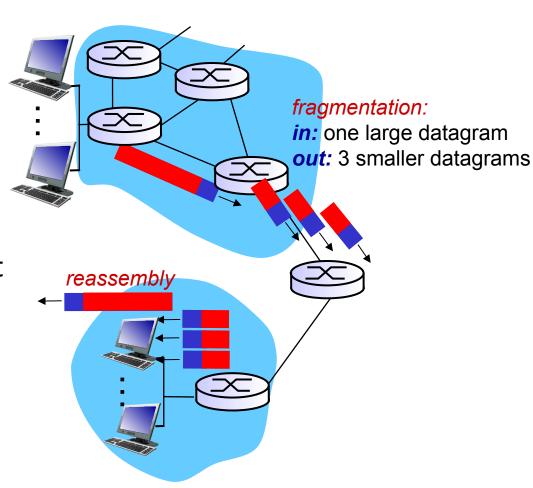

#### how much overhead?

- 20 bytes of TCP
- 20 bytes of IP
- = 40 bytes + app layer overhead

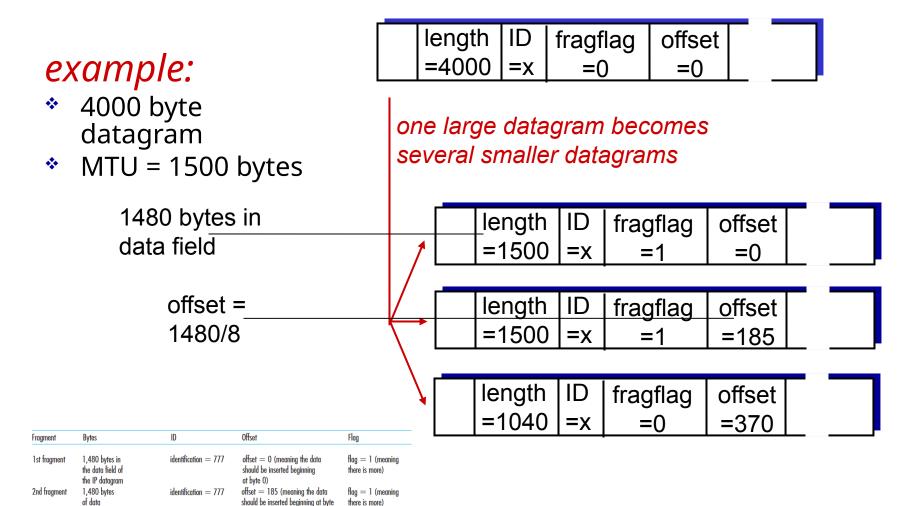

to visit.

# IP fragmentation, reassembly

- network links have MTU (max.transfer size) largest possible link-level frame
  - different link types, different MTUs
- large IP datagram divided ("fragmented") within net
  - one datagram becomes several datagrams
  - "reassembled" only at final destination
  - IP header bits used to identify, order related fragments

# \*\*\*IP fragmentation, reassembly

1,480. Note that  $185 \cdot 8 = 1,480$ )

flag = 0 (meaning this

is the last fragment)

offset = 370 (meaning the data

should be inserted beginning at byte

2.960. Note that  $370 \cdot 8 = 2.960$ )

identification = 777

3rd fragment

1,020 bytes

of data

(=3,980-1,480-1,480)

An IP packet of size 1600 bytes passes through network segment before it reaches its destination. The header size of this packet is 30 bytes. The maximum size of an IP packet in intermediate network (MTU) is 1400 bytes. How the IP packet would be fragmented in a router. Find all the information for each fragments.

- Original packet = 1600 B → data = 1600 30 = 1570 B
- MTU = 1400 B → max payload per fragment = 1400 30 = 1370 B
- Fragment offset is in 8-byte units ⇒ all but the last fragment's data must be a multiple of 8.

#### Choose payloads

- First fragment payload = largest ≤ 1370 that's multiple of 8 ⇒ 1368 B (8×171)
- Remaining data = 1570 1368 = 202 B (last fragment can be non-multiple of 8)

#### Fragment details

Frag	Total Length (B)	Header (B)	Data (B)	MF	Offset (8-byte units)	Byte range in original data
1	1398	30	1368	1	0	0–1367
2	232	30	202	0	<b>171</b> (1368/8)	1368–1569

RGP

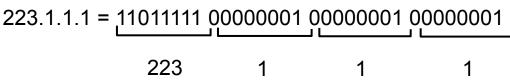

4.7 broadcast and multicast routing

Network Layer 4-48

### IP addressing: introduction

- IP address: 32-bit identifier for host, router interface
- interface: connection between host/router and physical link
  - router's typically have multiple interfaces
  - host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)
- IP addresses associated with each interface

### IP addressing: introduction

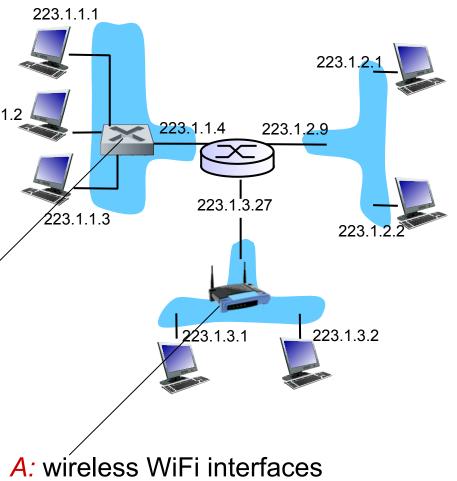

Q: how are interfaces actually connected?

A: we'll learn about that the

in chapter 5, 6.

A: wired Ethernet interfaces connected by Ethernet switches

For now: don't need to worry about how one interface is connected to another (with no intervening router)

connected by WiFi base station

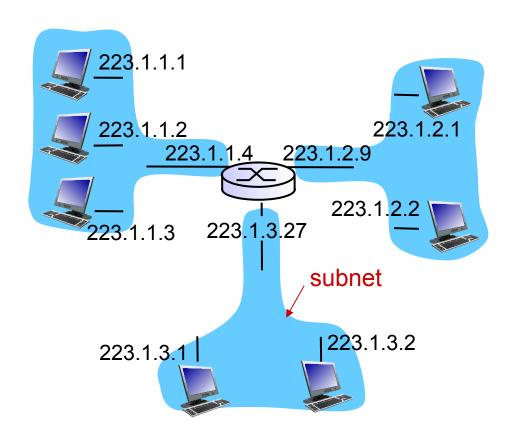

# Subnets

#### \*IP address:

- subnet part high order bits
- host part low order bits

#### \*what's a subnet?

- device interfaces with same subnet part of IP address
- can physically reach each other without intervening router

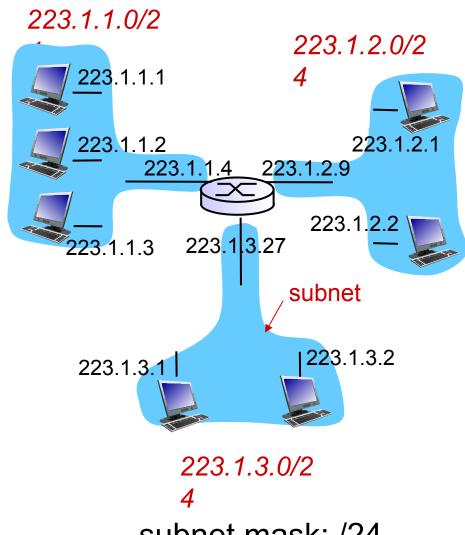

network consisting of 3 subnets

# Subnets

#### recipe

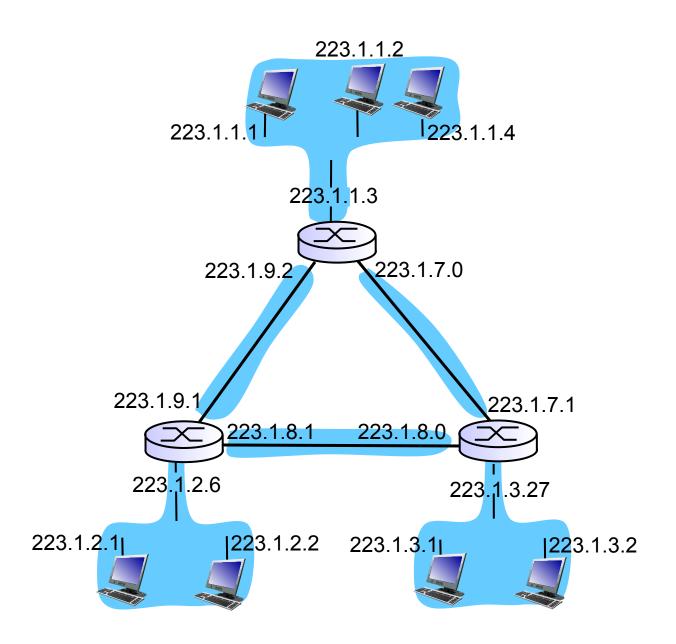

- to determine the subnets, detach each interface from its host or router, creating islands of isolated networks
- each isolated network is called a *subnet*

subnet mask: /24

# **Subnets**

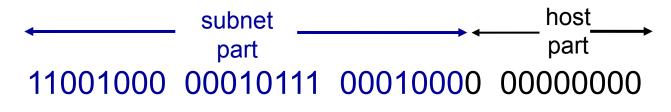

how many?

# IP addressing: CIDR

#### CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: a.b.c.d/x, where x is # bits in subnet portion of address

200.23.16.0/23

# IP addresses: how to get one?

Q: How does a *host* get IP address?

- hard-coded by system admin in a file
  - Windows: control-panel->network->configuration->tcp/ip->properties
  - UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from as server
  - "plug-and-play"

#### **DHCP: Dynamic Host Configuration Protocol**

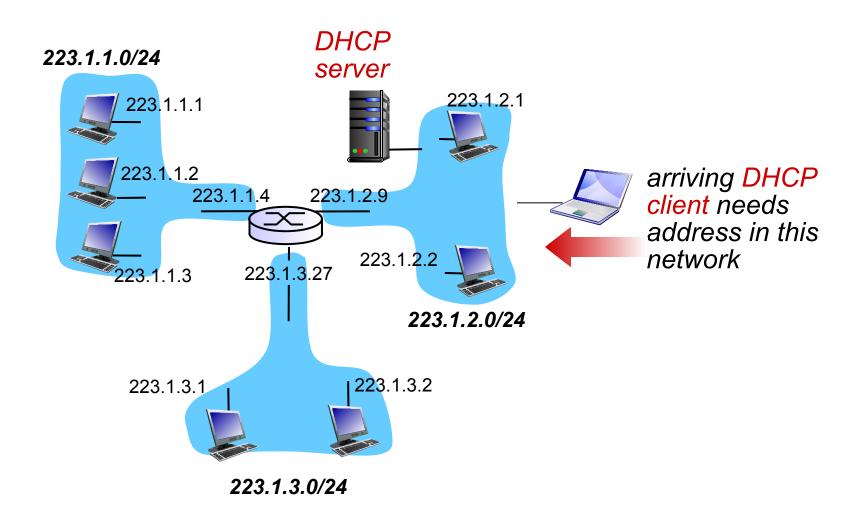

*goal*: allow host to *dynamically* obtain its IP address from network server when it joins network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network (more shortly)

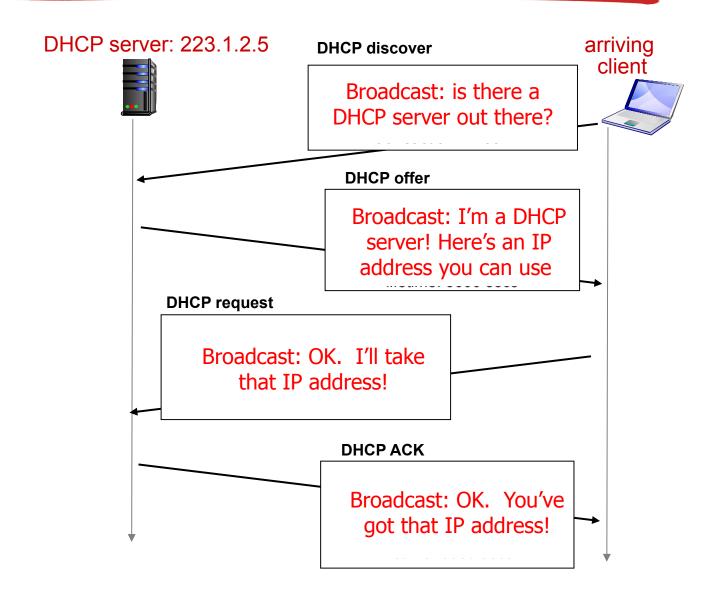

#### DHCP overview:

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

#### DHCP client-server scenario

# DHCP client-server scenario

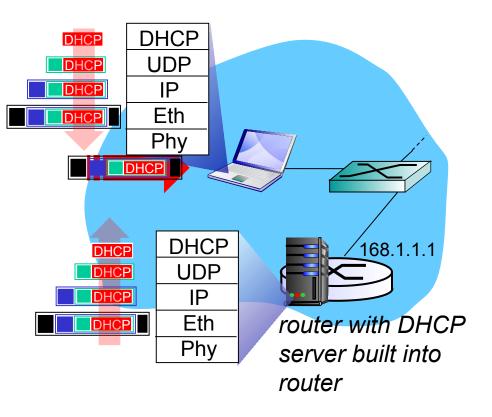

## DHCP: more than IP addresses

DHCP can return more than just allocated IP address on subnet:

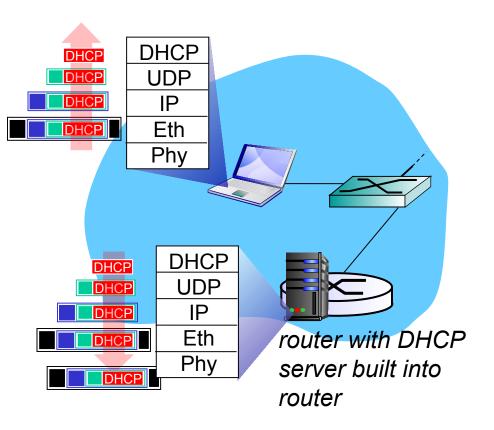

- address of first-hop router for client
- name and IP address of DNS sever
- network mask (indicating network versus host portion of address)

#### **DHCP**: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.1
- Ethernet demuxed to IP demuxed, UDP demuxed to DHCP

#### **DHCP**: example

- DCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to
- DHCP at client
   client now knows its
   IP address, name and
   IP address of DSN
   server, IP address of
   its first-hop router

# DHCP: Wireshark output (home LAN)

# IP addresses: how to get one?

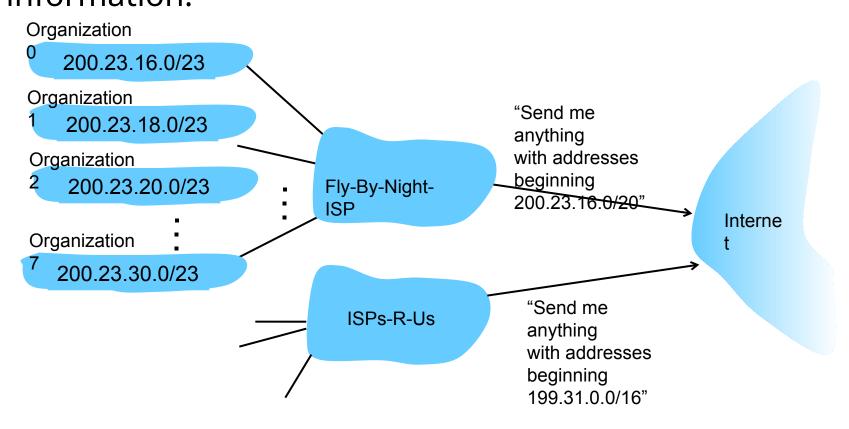

Q: how does network get subnet part of IP addr?

A: gets allocated portion of its provider ISP's address space

ISP's block	11001000	00010111	00010000	00000000	200.23.16.0/20
Organization 0 Organization 1					200.23.16.0/23 200.23.18.0/23
•					200.23.20.0/23
Organization 7	11001000	00010111	<u>0001111</u> 0	00000000	200.23.30.0/23

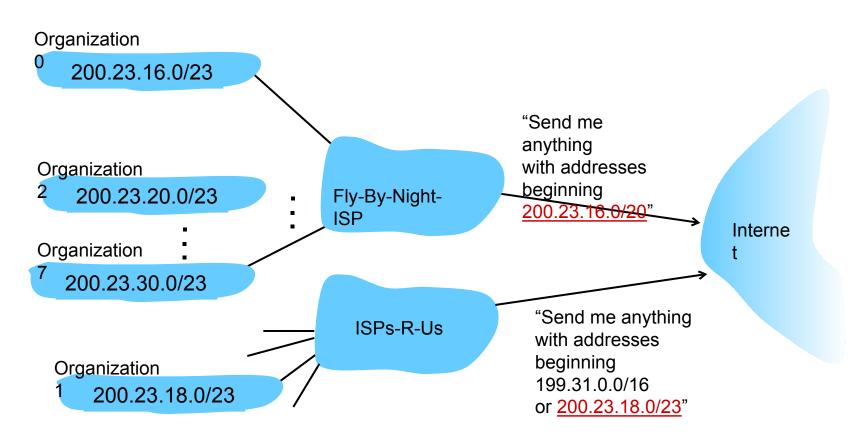

#### Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

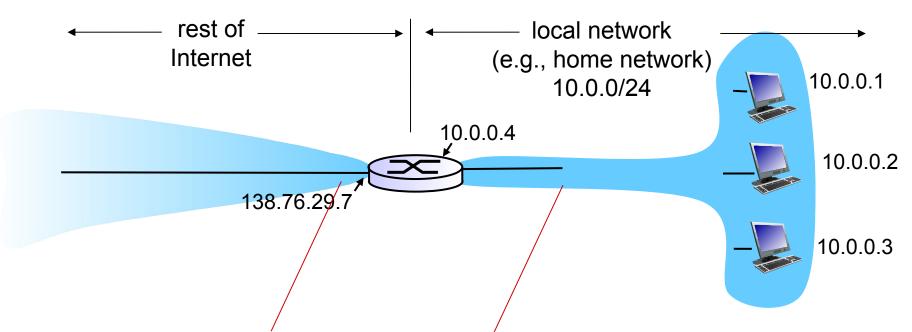

#### Hierarchical addressing: more specific routes

# ISPs-R-Us has a more specific route to Organization 1

#### IP addressing: the last word...

- Q: how does an ISP get block of addresses?
- A: ICANN: Internet Corporation for Assigned Names and Numbers http://www.icann.org/
  - allocates addresses
  - manages DNS
  - assigns domain names, resolves disputes

all datagrams leaving local network have same single source NAT IP address: 138.76.29.7, different source port numbers

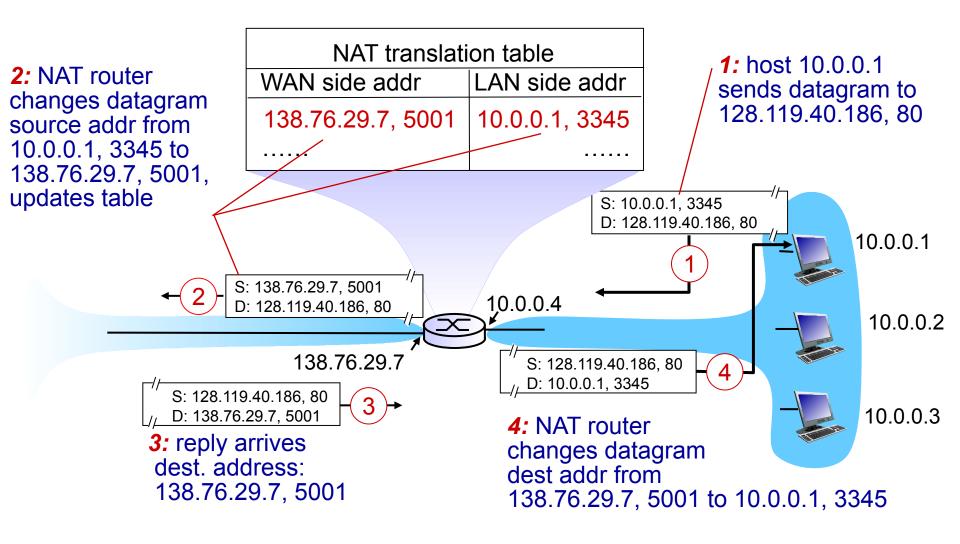

datagrams with source or destination in this network have 10.0.0/24 address for Network Layer 4-67

*motivation:* local network uses just one IP address as far as outside world is concerned:

- range of addresses not needed from ISP: just one IP address for all devices
- can change addresses of devices in local network without notifying outside world
- can change ISP without changing addresses of devices in local network
- devices inside local net not explicitly addressable, visible by outside world (a security plus)

#### implementation: NAT router must:

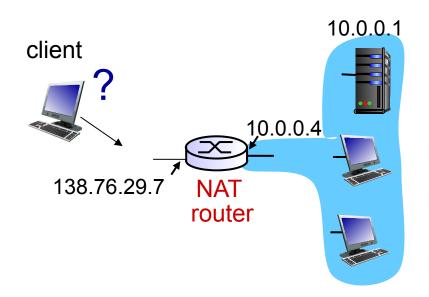

- outgoing datagrams: replace (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
   ... remote clients/servers will respond using (NAT IP address, new port #) as destination addr
- remember (in NAT translation table) every (source IP address, port #) to (NAT IP address, new port #) translation pair
- incoming datagrams: replace (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

- 16-bit port-number field:
  - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
  - routers should only process up to layer 3
  - violates end-to-end argument
    - ➢NAT possibility must be taken into account by app designers, e.g., P2P applications
  - address shortage should instead be solved by IPv6

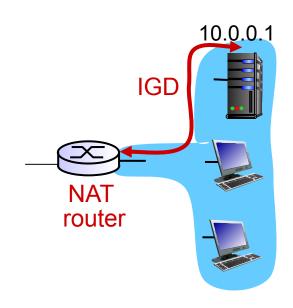

# NAT traversal problem

- client wants to connect to server with address 10.0.0.1
  - server address 10.0.0.1 local to LAN (client can't use it as destination addr)
  - only one externally visible NATed address: 138.76.29.7
- \* solution1: statically configure NAT to forward incoming connection requests at given port to server
  - e.g., (123.76.29.7, port 2500)
     always forwarded to 10.0.0.1 port 25000

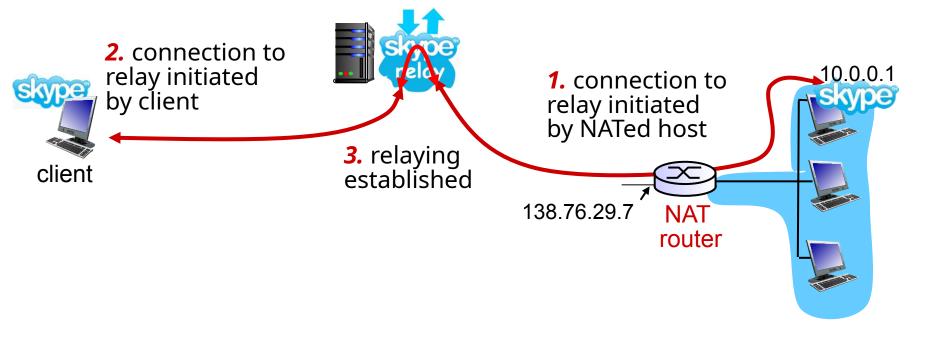

# NAT traversal problem

- solution 2: Universal Plug and Play (UPnP) Internet Gateway Device (IGD) Protocol. Allows NATed host to:
  - learn public IP address (138.76.29.7)
  - add/remove port mappings (with lease times)
  - i.e., automate static NAT port map configuration

# NAT traversal problem

- solution 3: relaying (used in Skype)
  - NATed client establishes connection to relay
  - external client connects to relay
  - relay bridges packets between to connections

# Chapter 4: outline

- 4.7 broadcast and multicast routing

#### ICMP: internet control message protocol

- used by hosts & routers to communicate networklevel information
  - error reporting: unreachable host, network, port, protocol
  - echo request/reply (used by ping)
- network-layer "above" IP:
  - ICMP msgs carried in IP datagrams
- ICMP message: type, code plus first 8 bytes of IP datagram causing error

<u>Type</u>	Code	description
0	0	echo reply (ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	2	dest protocol unreachable
3	3	dest port unreachable
3	6	dest network unknown
3	7	dest host unknown
4	0	source quench (congestion
		control - not used)
8	0	echo request (ping)
9	0	route advertisement
10	0	router discovery
11	0	TTL expired
12	0	bad IP header

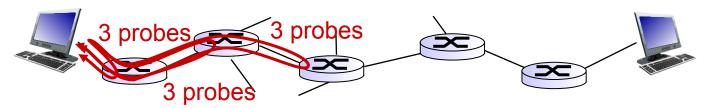

## Traceroute and ICMP

- source sends series of UDP segments to dest
  - first set has TTL =1
  - second set has TTL=2, etc.
  - unlikely port number
- when nth set of datagrams arrives to nth router:
  - router discards datagrams
  - and sends source ICMP messages (type 11, code 0)
  - ICMP messages includes name of router & IP address

when ICMP messages arrives, source records RTTs

#### stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns
   ICMP "port
   unreachable" message
   (type 3, code 3)
- source stops

# **IP Security**

- To communicate securely in the nonsecure public Internet. E.g. VPN
- \* The services provided by an IPsec session include:
- Cryptographic agreement.
- Encryption of IP datagram payloads.
- Data integrity.
- Origin authentication.

Consider a router that interconnects three subnets: Subnet 1, Subnet 2, and Subnet 3. Suppose all of the interfaces in each of these three subnets are required to have the prefix 223.1.17/24. Also suppose that Subnet 1 is required to support at least 60 interfaces, Subnet 2 is to support at least 90 interfaces, and Subnet 3 is to support at least 12 interfaces. Provide three network addresses (of the form a.b.c.d/x) that satisfy these constraints.

Consider sending a 2400-byte datagram into a link that has an MTU of 700 bytes. Suppose the original datagram is stamped with the identification number 422. How many fragments are generated? What are the values in the various fields in the IP datagram(s) generated related to fragmentation?

Suppose datagrams are limited to 1,500 bytes (including header) between source Host A and destination Host B. Assuming a 20-byte IP header, how many datagrams would be required to send an MP3 consisting of 5 million bytes? Explain how you computed your answer.

Suppose two packets arrive to two different input ports of a router at exactly the same time. Also suppose there are no other packets anywhere in the router.

- a. Suppose the two packets are to be forwarded to two different output ports. Is it possible to forward the two packets through the switch fabric at the same time when the fabric uses a shared bus?
- b. Suppose the two packets are to be forwarded to two different output ports. Is it possible to forward the two packets through the switch fabric at the same time when the fabric uses a crossbar?
- c. Suppose the two packets are to be forwarded to the same output port. Is it possible to forward the two packets through the switch fabric at the same time when the fabric uses a crossbar?
